Earned Schedule

...application to Small Projects

The ES idea is to determine the time at which the EV accrued should have occurred.
Abstract

Stop work and down time conditions, sometimes occurring for small projects, impact the values computed for Earned Schedule indicators. The distorted values, in turn, have the potential to affect management decisions. To address the problem, a special calculation method for handling these conditions is presented and examined using four sets of notional data. Comparison to the normal ES calculation results indicate significant improvement from using the special calculation method.

Introduction

- **ES introduced in 2003**

  The ES idea is to determine the time at which the EV accrued should have occurred.
Introduction

- $ES = C + I$
  
  where $C$ is number of periodic time units of the PMB for which $EV \geq PV_C$
  
  and $I = [(EV - PV_C) / (PV_{C+1} - PV_C)] \times 1$ period

- $SV(t) = ES - AT$

- $SPI(t) = ES / AT$

- $IEAC(t) = PD / SPI(t)$
Introduction

- ES has provided analysis and forecasting capability previously not believed possible
  - Reliable indicators
  - Prediction and Forecasting
  - Schedule Adherence
    - Impediments/Constraints
    - Potential rework
    - Forecasting improvement
    - Schedule management indicator
    - Calculation – out of sequence EV accrued & rework forecast
Introduction

- **However** - conditions occurring for small, short duration, projects can cause error for ES indicators, and forecasts
- **Down Time** – *periods within the schedule where no work is planned*
- **Stop Work** – *periods during execution where management has halted performance*
Down Time & Stop Work

**EV & PV Data with Stop Work & Down Time**

- Periods 6 & 7 indicate management imposed a stop work
- Periods 15 - 18 show that no work was planned

Note: EV & PV data are preceded by “i.” The i denotes discontinuity; the data are interrupted.
Down Time & Stop Work

- When management imposes a Stop Work the opportunity has been removed for accruing EV
  - PV values for periods 6 & 7 are unaffected
- Down Time extends the planned period of performance.
  - Management has the prerogative to work, instead.
  - For data shown, work was performed during Down Time
  - If plan had been followed, “XX” would appear for the iEV_{cum} entries
## Schedule Performance Indicators

<table>
<thead>
<tr>
<th>Normal Indicators</th>
<th>Special Indicators</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPI(t)wk</td>
<td>SPI(t) cum</td>
</tr>
<tr>
<td>0.4503</td>
<td>0.6084</td>
</tr>
<tr>
<td>0.0000</td>
<td>0.5070</td>
</tr>
<tr>
<td>0.0000</td>
<td>0.4346</td>
</tr>
</tbody>
</table>

### Stop Work Indicators

- $SV(t)_{wk}$ & $iSV(t)_{wk}$ both show -1.0 for Stop Work periods
- $SPI(t)_{wk}$ & $iSPI(t)_{wk}$ both equal 0.0
- $SPI(t)_{cum}$ decreases while $iSPI(t)_{cum}$ does not
- $SV(t)_{cum}$ equals $iSV(t)_{cum}$ without *Down Time*
- $iSV(t)_{cum}$ + *Down Time* includes potential to work
## Schedule Performance Indicators

<table>
<thead>
<tr>
<th>Normal Indicators</th>
<th>Special Indicators</th>

<td>0.8225</td>
</tr>
</tbody>
</table>

### Down Time Indicators

- \(iSV(t)_{wk} = SV(t)_{wk} + \) Down Time scheduled for the week
- \(SPI(t)_{wk} = \) iSPI(t)\(_{wk}\)
- \(SPI(t)_{cum} < iSPI(t)_{cum}\) due to previous Stop Work
- \(iSV(t)_{cum}DT = SV(t)_{cum} + \) Total Down Time
- \(iSV(t)_{cum}w/oDT = iSV(t)_{cum}DT - \) Down Time Remaining
Schedule Performance Indicators

- Relationship between normal and special schedule performance indicators

  - \( iSV(t)_{\text{per}} = SV(t)_{\text{per}} + DT_{\text{per}} \)
  - \( iSV(t)_{\text{cum}} DT = SV(t)_{\text{cum}} + DT_T \)
  - \( iSV(t)_{\text{cum w/o DT}} = iSV(t)_{\text{cum}} DT - DT_R \)
  - \( iSPI(t)_{\text{per}} = SPI(t)_{\text{per}} \)
  - \( iSPI(t)_{\text{cum}} = SPI(t)_{\text{cum}} \cdot (AT / (AT - SW)) \)

Note: “Normal” refers to the results from the simple ES calculator.
Schedule Performance Indicators

- The key point - when *Stop Work* and *Down Time* conditions occur, the normal indicators do not accurately portray performance and have the potential to cause inappropriate management decisions.

- The special indicators provide better management information.
  - $iSPI(t)_{cum}$ & $iSV(t)_{cum}$ DT indicate the true schedule performance.
  - $iSV(t)_{cum}$ w/oDT depicts position of the project should *Down Time* be compressed out.
Forecasts

- Before proceeding it is worthy to note that ES forecasts using the normal index values will always converge to the actual duration.
- Well then ... if this is the case ... *Why bother?*
- I will show the improvement is significant enough to warrant using the special calculation method.
- The idea of the special calculation is fairly simple ... but has some complexity.
Forecasts

- Simply stated – an initial forecast is made as if interrupting conditions are not present. The interruption effects are then added to this initial forecast as they occur.

- The initial forecast is
  \[ \text{IEAC}(t)_{sp1} = (PD - DT_T) / \text{iSPI}(t)_{cum} \]
  where \( DT_T \) = total number of down time periods

- The running total of stop work periods (SW) is added creating a second forecast expression
  \[ \text{IEAC}(t)_{sp2} = (PD - DT_T) / \text{iSPI}(t)_{cum} + SW \]
Forecasts

- Next $DT_T$ is added. As down time periods occur they are totaled ($DT_L$) and subtracted.
- When $IEAC(t)_{sp2} < PD$, the number of down time periods between the forecast and PD are counted ($DT_C$) and subtracted
- The special forecasting formula becomes
  
  \[ IEAC(t)_{sp} = \frac{(PD - DT_T)}{iSPI(t)_{cum}} + SW + DT_T - DT_L - DT_C \]

*Stop Work/Down Time Forecast*

- Observe the difference for *Stop Work* periods 6 & 7 …how the normal forecast dramatically increases
- For the *Down Time* periods (15-18) …note that the special forecast behaves with less variation through to completion
Case Comparisons

- The normal and special forecasts for four scenarios of *Stop Work* and *Down Time* conditions are compared using a time plot of the forecast values and a column chart of the variation (standard deviation) from actual final duration
  - The time plot of the forecasts provide a visual of the differences
  - The column chart depicts convergence through the use of four performance ranges: 10%-100%, 25%-100%, 50%-100%, 75%-100%
Case Comparisons

- Four performance scenarios compared are
  - Case 1 is an early finish project with a three week stop work condition
  - Case 2 is a late finish with work stopped during four weeks of down time
  - Case 3 is a late finish with work accomplished through four weeks of down time
  - Case 4 is a late finish having two weeks of stop work followed by four weeks of worked down time
Case #1 Comparison

- **Early Finish – 3 week stop work (11-13)**
  - The normal forecast overshoots and then converges
  - The special forecast converges smoother and sooner
Case #2 Comparison

Late Finish – 4 periods of down time (15-18)

- The normal forecast has a larger increase for the down time and requires longer to converge to the final duration
**Case #3 Comparison**

![Graph showing forecast duration and standard deviation comparison for Case #3.](image)

- **Late Finish** – work through 4 periods of down time (15-18)

  - The special forecast has less variation and more smoothly converges to the final duration
Case #4 Comparison

Late Finish – 2 period stop work (6-7) and work 4 down time periods (15-18)

- The stop work periods cause more variation for the normal than for the special forecast method
- The special forecast converges much more rapidly
Case Comparisons

- The special case forecasts are more accurate for every set of computed values after the first period.
- The column charts clearly indicate better forecasting and convergence for all data ranges.
- When interruptions of *Stop Work* and *Down Time* are encountered the special forecasting method can be expected to produce more reliable results.
Summary

- Over several years of research and application, ES has shown to be a reliable schedule analysis extension to EVM
- For large projects, *Stop Work* and *Down Time* conditions for small portions of the project may not have much impact on the ES indicators and forecast values
- For small projects, the interrupting conditions will distort ES indicators and forecasts and possibly impact management decisions
Summary

- Special calculation method was created for the conditions of *Down Time* and *Stop Work*
- Comparisons of normal and special method calculations were made for four sets of performance data having DT and SW periods
- For the four performance scenarios, the forecast graphs and column charts clearly indicate the special forecasting method produced better results
Final Comment

- Although the special method calculations are not difficult, they are tedious ...and mistake prone
- To facilitate uptake of the special method a calculator (ES Calculator vs1b (Special Cases)) is freely available from the ES website (www.earnedschedule.com)
